Quantitative Analysis of Pollution Indicator and Pathogenic Bacteria in River Tawi, J&K (India)

Roopma Gandotra[1], Payal Andotra[1], Hina[1] and J.P. Sharma[2]

[1]Department of Zoology, University of Jammu, Jammu, India. [2]IIIM, Canal Road, Jammu, India.

(Received: 14 January 2009; accepted: 24 February 2009)

The present study aimed at the assessesment of water quality and to quantify microorganisms of health concerns of river Tawi - the main source of drinking water supplies for Jammu city and its outskirts. Seasonal changes in quantitative estimation of bacterial load (SPC & MPN) at four different stations of river Tawi showed a significant change. Various bacterial species viz. *Escherichia coli*, *Salmonella* sp. & *Pseudomonas* sp. were isolated from water as well as fish fauna of river Tawi, with the help of biochemical tests and further confirmation was done by molecular analysis (PCR). The correlation ($p<0.05$) of bacterial population with physico-chemical parameters was also enumerated and it was found to be positively correlated with temperature & alkalinity and negatively with pH, DO & FCO_2 .

Keywords: River Tawi, Bacterial load, Physico-chemical, Correlation, PCR.

River Tawi is the main source of drinking water supplies for Jammu city and its outskirts. As river is being polluted day by day (with sewage and other effluents), it is therefore necessary to know the degree of pollution load so as to assess its potability. For assessment of water quality, it is not only the physico-chemical characteristics but information whether river conforms to standard of microbiological water quality is more significant (APHA, 1998). Coliform count and *Escherichia coli* detection in particular, remains the major and most reliable tool in the assessment of the health risks posed by pathogens in water (Brenner *et al*. 1993, Grant 1997, Byamukama *et al*. 2000).

Methodology

Sampling sites

During the study period (April 06 - March 07), four sampling stations were selected along the river Tawi (within the city limits of Jammu) viz., Station I (Har ki Pouri), Station II (Peer Kho), Station III (Gujjar Nagar) and Station IV (Bhagwati Nagar). Station I has negligible sewage entry where as there is a regular increase in sewage entry as we move from Station I to Station IV.

Physico-chemical analysis

Physico-chemical analysis viz., Temperature, pH, DO, FCO_2 & alkalinity was done according to the procedures recommended by American Public Health Association (APHA, 1998). Samples were collected monthly from all the stations.

Bacteriological analysis

Quantitative estimation of bacteria by Standard Plate Count (SPC/ml of facultative aerobic bacterial count) & Most Probable Number (MPN/100ml) count or coliform count methods.

Qualitative estimation of bacteria includes

(i) Isolation and growth of bacteria includes dilution of sample (either water or swabs

from different organs i.e. skin, gills & intestine of fishes) followed by streaking on nutrient agar plates again & again till the appearance of single colonies.

(ii) Identification on the basis of cultural characteristics, staining reactions and biochemical reactions (Bergey's manual 8th edition, 1974; Collins & Lyne, 1985 and Austin & Austin, 1987).

Molecular analysis

Specific PCR assay was performed using chromosomal DNA. The cultures were grown in 3-5 ml of LB broth (Hi media, India) at 37°C for 24 hrs. 1 ml of grown culture was pelleted down, supernatant drained out and the pellet suspended in 300 ml of mixture of STE buffer, SDS, BSA and ß-merceptoethanol. After vortexing, 250µl ice cold 7.5 M ammonium acetate was added, incubated on ice and centrifuged (after adding 500 µl chloroform) at 7000 rpm for 15 minutes. Aqueous phase again centrifuged after addition of chloroform, repeated thrice. Precipitation was effected by 7.5 M ammonium acetate and ethanol. Pellet was air dried & resuspended in 30µl of TE.

Two pairs of primers were designed for PCR assay: QVR184 (5'ACGCATTTTG CGTTTATTCC 3') & QVR185 (5'GGATT GCCTG GCTCATAAAC 3') for *Salmonella* flg B gene and QVR201 (5'GGCTTCTGTCAA CGCTGTTT3') & QVR202 (5'ACAGTTTTCGC GATCCAGAC 3') for *E. coli* uidA gene.

PCR was performed using extracted DNA. The reaction assay of 20 µl contained 10X PCR buffer, 200µM dNTP mixture, 10 pmoles of each primer, 1-10 ng of template DNA and 1U of Taq polymerase. The reactions were performed in Mastercycler (Eppendorf, Germany). PCR programme was set up as follows: Initial denaturation at 72°C for 3 min. followed by 30 cycles of denaturation (94°C for 15 sec.), annealing (60°C for 45 sec.) and extension (72°C for 15 sec.). Final extension was allowed at 72°C for 5 min.

A PCR reaction with all reaction components without DNA was run as a negative control to rule out any carry over contamination. The PCR products were run on 1% agarose gel and visualized under UV transilluminator. The primers used for *Salmonella* sp. yielded a specific PCR product of 752 bp and those for *E. coli* yielded a PCR product of 293 bp**.**

Statistical analysis

Bacterial load (SPC & MPN count) and Physicochemical parameters (temperature, pH, DO, FCO_2 & alkalinity) were statistically analysed with the help of Pearson correlation coefficient (calculated by Minitab software). Statistical significance was set at $p < 0.05$.

RESULTS AND DISCUSSION

Correlation between bacterial load and physico-chemical parameters

The data and correlation of bacterial load (SPC & MPN) & physico-chemical parameters presented in Tables 1, 2, 3 & 4 clearly revealed that the highest bacterial load (SPC as well as MPN) was recorded at sampling sites III & IV (high level of sewage contamination) as compared to I & II. Further, Station IV had significantly higher load than Station III. The present observations are in line with the studies of Austin & Austin (1985) and Agbogu *et al*. (2006), who also associated the high levels of bacterial load with the amount of sewage contamination.

Temperature showed positive correlation with SPC (r=0.60,0.39,0.55,0.70) and MPN (r=0.73,0.81,0.76,0.39) at all the sampling stations (I-IV). A significant correlation ($p<0.05$) was noticed between SPC and temperature at Station I & IV and insignificant ($p>0.05$) at Station II & III. MPN was also found to be significantly correlated ($p<0.05$) with temperature at Station I, II & III, where as at Station IV it showed insignificant ($p>0.05$) correlation with temperature. In tune with the present observations Sharma (1993), Gupta (1996) and Al-Harbi (2003) also held that the bacterial count of a water body bears a direct correlation with water temperature.

pH showed negative correlation (r = -0.54, -0.61, -0.30, -0.75) with SPC at all the stations (Station I–IV). Both the parameters recorded a significant correlation ($p<0.05$) at Station II & at Station IV and insignificant correlation ($p>0.05$) at Station I & III. The data further revealed a negative correlation (r= -0.81, -0.56, -0.74, -0.01) between pH and MPN at all the experimental stations (I-IV). MPN recorded significant relation ($p<0.05$) with pH at Station I, II & III where as at Station IV, it showed insignificant ($p>0.05$) correlation. Contrary to the

Statistical Analysis

present observations, Sharma (1993) and Gupta (1996) reported no marked correlation between seasonal pH value and bacterial count in pond water samples studied by them.

With Dissolved oxygen (DO) SPC, showed a negative correlation (r = -0.50, -0.37, -0.35, -0.56) in all the experimental stations. DO recorded significant ($p<0.05$) relationship with

SPC at Station IV (highly polluted) and insignificant ($p>0.05$) at Station I, II & III. The results further suggest that there is a negative correlation between DO and MPN ($r = -0.59, -0.79, -0.73, -0.36$) at all the experimental stations. The present observations very clearly indicate that there is a perceptible increase in MPN values with increase in dissolved oxygen. DO recorded a significant relationship ($p<0.05$) with MPN at Station I, II & III whereas insignificant ($p>0.05$) relation was observed at Station IV.

Free carbon-dioxide (FCO_2) was found to be absent at Station I (with minimum pollution level), so no correlation was noticed between SPC and FCO_2 where as negative correlation ($r = -0.15, -0.23, -0.72$) was observed between the two at Station II, III & IV. SPC was significantly ($p<0.05$) correlated with FCO_2 at Station IV and insignificantly ($p>0.05$) at Station II & III. MPN showed negative correlation ($r = -0.30, -0.26, -0.55$) with FCO_2 at all the stations (II, III & IV) except Station I where no correlation was observed between MPN & FCO_2 due to the complete absence of FCO_2. With FCO_2, MPN correlated significantly ($p<0.05$) at Station IV whereas at Station II & III it showed insignificant ($p>0.05$) correlation.

A negative correlation (r = -0.46, -0.18, -0.26) was recorded between SPC and Alkalinity at Station I, II & III whereas at Station IV a positive correlation (r=0.35) was observed. An insignificant ($p>0.05$) correlation was noticed between the two at all the selected stations (I–IV). At Station II & IV positive correlation (r = 0.12, 0.25) and at Station I & III negative correlation (r = -0.59, -0.13) was observed between MPN & Alkalinity. At Station I, MPN showed significant correlation ($p<0.05$) with Alkalinity whereas at Station II, III & IV, an insignificant ($p>0.05$) correlation was recorded between the two.

Bacterial isolates

During the present study period, 141 bacteria were isolated as pure cultures. Out of these, 97 bacteria were isolated from water and 44 were isolated from fish samples. Among 97 isolates (from water), 34 were unidentified and 65 were identified whereas from 44 isolates of fish samples, 16 were unidentified and 28 were identified. Out of 65 identified isolates of water, 33 were *E. coli*, 19 were *Salmonella* sp., 11 were *Pseudomonas* sp. Among 28 identified isolates of fish, 21 were *E. coli*, 6 were *Salmonella* sp. and 1 belonged to genus *Pseudomonas* (Table 5). The organwise distribution of bacterial isolates is given in Table 7. Bacterial isolates were identified on the basis of biochemical tests (Table 8) and further confirmation was with the help of PCR (Fig. 1, 2 & 3). The primers used for *Salmonella* sp. yielded a specific PCR product of 752 bp and the primers used for *E. coli* yielded PCR product of 293 bp. The method presently used has already been developed and validated by Biotechnology division, IIIM (Indian Institute of Integrative Medicine), Jammu (J&K).

Identified bacterial species i.e. *E. coli, Salmonella* sp. and *Pseudomonas* sp. (Fig. 4, 5 & 6) were isolated from water as well as from resident fishes of river Tawi, thereby suggesting the impact of surrounding environment on the composition of the microflora of fish. Also, faecal coliforms in fish reflect the level of pollution of their environment, as the normal flora of fish does not include coliforms. This observation gets support from the findings of Shewan and Hobbs (1967), Cohen and Shuval (1973), Sivakami *et al.* (1996) and Apun *et al.* (1999), who also suggested the impact of aquatic environment on the microflora of inhabiting fish fauna.

Fig. 4. *Escherichia coli* showing green metallic sheen on EMB detection medium

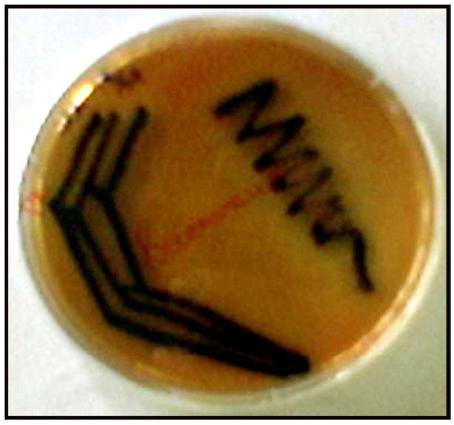

Fig. 5. *Salmonella* showing black growth on DCA detection medium

Fig. 6. *Pseudomonas* showing fluorescent growth on CAB detection medium

During the present study, *Salmonella* sp. was recorded both from Station III and Station IV (polluted areas) and no record was observed from Station I or Station II (less polluted). The data further revealed that its number was highest in Station IV (highly polluted station) as compared to Station III (moderately polluted) -Table 6. Present observations are supported by the findings of Efstratiou *et al*. (1998), who also reported maximum *Salmonella* from highly polluted sites.

CONCLUSION

Both physico-chemical and bacteriological parameters revealed an alarming trend of increase as we move from Station I to Station IV, thereby indicating deteriorating quality of river water & its edible fish fauna. The increasing pollution at Station III & IV also indicate the maximum load of pathogens in these spots which may prove health hazardous. Thus, keeping in view the public health, there is an urgent need for regular monitoring of river Tawi in order to avoid water borne diseases.

ACKNOWLEDGEMENTS

The authors are grateful to Department of Zoology, University of Jammu (J&K), India for their assistance, whenever needed. The co-operation and efforts of the staff of the Biotechnology Division, IIIM (Indian Institute of Integrative Medicine), Jammu (J&K) are duly acknowledged.
