(Received: 10 December 2016; accepted: 25 January 2017)

Swine pasteurellosis is an acute infectious disease and is considered to be one of the most economically important diseases in Asia particularly in South and South East Asia leading to huge economic loss in livestock industry. A study was conducted to analyze the histopathological alterations caused by cytotoxins released by Pasteurella multocida serotype B, which caused Swine pasteurellosis in descript as well as nondescript pigs of Chhattisgarh, India. Affected animals exhibited pyrexia, dullness, staggering gait, anorexia, serous nasal discharge and dyspnoea. Typical lesions of oedematous swellings noted in the pharyngeal region. Case fatality rate was 95% in adult animals and 100% in piglets. The causative organism, Pasteurella multocida was isolated and characterized by biochemical tests and the detection of the KMT1, CapB, toxA, and ompH genes was performed using Polymerase Chain Reaction (PCR). Gross lesions included severe pneumonia and haemorrhages in lungs, petechial haemorrhages on serous membranes and other visceral organs. Lymph nodes were enlarged, oedematous and haemorrhagic. The histopathological lesions developed in lungs were typical fibrinous bronchopneumonia, multifocal suppuration and severe thickening of pleura. Heart showed presence of thrombi, haemorrhages and necrosis of myocardium. Hepatic architecture showed server haemorrhages and necrosis while kidneys and spleen showed degenerative and necrotic changes.

Keywords: Swine, Pathology, Swine Pasteurellosis, Pneumonic pasteurellosis.

Pasteurella multocida is of substantial economic significance in the livestock industry. It is an important principal animal pathogen for over a century and is becoming crucial as human pathogen¹ leading to a disease process termed Pasteurellosis. Pasteurella multocida B:2, which causes haemorrhagic septicaemia (HS) of ruminants, is believed to enter the host via respiratory and oral routes. The present study describes the pathological alterations following natural infection in pigs. It is a peracute disease and is considered to be one of the most economically important diseases in Asia particularly in South and South East Asia leading to huge economic loss in livestock industry. The clinical indication of this disease is often characterised by rapid course of high fever, respiratory distress, dullness, depression and followed by death generally within a day of infection². Pathogenesis of P. multocida is a complex interaction between host specific factors and specific bacterial virulence factors; therefore,
understanding the disease pathogenesis is complex and depends on the bacterial strain, the animal model and their interactions. The key virulence factors identified in *Pasteurella multocida* include capsule, lipopolysaccharides, surface adhesions, iron regulated and iron acquisition proteins. The protein toxin from *Pasteurella multocida* cause necrotic changes in vascular endothelium and induce all of the major symptoms in domestic livestock.

**MATERIALS AND METHODS**

Studies on outbreaks of swine pasteurellosin in descript and non-descript pigs was attended in Raipur, Durg and Rajnandgaon district in Chhattisgarh state, India, during rainy season of 2012. The affected animals were off fed and had high fever (41-42°C). About 95% mortality in affected pigs occurred. The infected pigs were examined clinically. Detailed necropsy was conducted and gross lesions were recorded. Blood and tissue samples were collected aseptically for bacterial isolation. Further the isolates were confirmed by biochemical tests and molecular characterization by PCR by using following sets of primers targeting KMT1, CapB, toxA, and ompH genes. The pairs of *Pasteurella multocida* specific primers were synthesized from Sigma Aldrich Chemicals, USA. Primer sequences are as follows:

- F KMT1SP6 5′- GCT GTA AAC GAA CTC GCC AC - 3′
- R KMT1T7 5′- ATC CGC TAT TTA CCC AGT GG – 3′
- F CAPB 5′-CAT-TTA-TCC-AAG-CTC-CAC-C-3′
- R CAPB 5′-GCC-CGA-GAG-TTT-CAA-TCC-3′
- F toxA 5′- CGT GAA CTG CGT ACT CAA-3′
- R toxA 5′-AAG AGG AGG CAT GAA GAG-3′
- F OmpH 5′-ACTATGAAAAAGACAATCGTAG-3′
- R OmpH 5′-GATCCATCTTGTGCAACATATT-3′

Further, the tissue samples from heart, lungs, liver, spleen, kidneys and Lymph nodes were collected in 10% Formal saline solution for histopathological studies. Morbid tissue samples then processed by routine histopathological techniques and stained with haematoxylin and eosin stains.

**RESULTS AND DISCUSSIONS**

A total of 13075 samples were collected during the study period. Typical cases of oedematous swellings noted in the pharyngeal region, these swellings spread to the ventral cervical region and brisket of adult pigs. On post-mortem examination, Petechiae and frothy exudates were present in trachea and bronchi. Petechiae were seen all over the serous membranes and peritoneum. There was hydrothorax with accumulation of straw coloured fluid (Fig. 1). Endocarditis was observed in the heart, Lungs showed severe consolidation along with the presence of multiple focal haemorrhages. In chronic cases marbled appearance of lungs were seen (Fig.2). Spleens from most of the dead pigs were very much enlarged. Liver and kidneys were swollen and contained petechial haemorrhages. There was presence of haemorrhagic enteritis. Lymph nodes were enlarged, oedematous and haemorrhagic. Microscopically, Lungs showed typical fibrinous bronchopneumonia, multifocal suppuration, Septae were thickened with fibrin, combined with cellular...

**Fig. 1.** Photograph showing petechial haemorrhages on serous membranes and hydrothorax with presence of straw coloured fluid

**Fig. 2.** Photograph showing marbled appearance of lungs, rubbery consistency, thickening of pleura and sub-pleural haemorrhages
infiltration and edema (Fig.3). Alveoli were filled with fibrinous exudate, erythrocytes and polymorphonuclear cells. Pleura was severely thickened. There were sub-pleural haemorrhages. Heart of some pigs showed presence of thrombi, Haemorrhages and necrosis of myocardium. Glomeruli and kidney tubules showed haemorrhages and necrotic changes. Severe congestion and haemorrhages were observed both in cortex and medulla of lymphnodes. There were haemorrhages and necrosis in Liver. The bacteriological isolation yielded bipolar Gram negative cocccobacillary organisms. The isolates of Pasteurella multocida tested by Pasteurella multocida species specific PCR (PM-PCR) were found to give an amplified product of 460 bp size using primer KMT1SP6 and KMT1T7 (Fig.4). Three pairs of primer sets (CAPA, CAPB and CAPD) were used in the capsular PCR analysis of different isolates of Pasteurella multocida. However, only primer pair of CAPB resulted in the amplification of a single band of 590 bp representing the capsular type B of Pasteurella multocida (Fig.). All the isolates in present study were associated with pneumonia were of capsular type B and yielded same amplicon size of 590 bp. On amplification using ompH-specific primer, a PCR product of the expected size of 1.2 kb was obtained.

*Pasteurella multocida* is considered a commensal organism in the upper respiratory tract and tonsils and causes disease outbreaks in swine, cattle, buffalo, sheep, and goats under extreme environmental conditions, or in animals immunosuppressed by viral infections. This organism is the most common pathogen isolated from pigs housed under poor husbandry conditions, eg, overcrowding and poor ventilation. The high mortalities observed in many outbreaks of swine pasteurellosis in India. Similar outbreak of haemorrhagic septicaemia in pig herd has been reported earlier with variable degree of necrotic myositis. The ulcerative skin lesions were absent during recent outbreak. Oedematous swellings were noted in the pharyngeal region of some of the infected pigs which is the predominant manifestation cattle and buffaloes. *P. multocida*
type B:2, is responsible for hemorrhagic septicemia in dairy cattle and buffalo and many outbreaks are reported every year from all over India suggesting that this serotype is transmitted between bovine species and swine. The protein toxin from Pasteurella multocida cause necrotic changes in vascular endothelium and induce all of the major symptoms in infected animals. The pathological modifications viz. generalized lymphadenopathy, submandibular and brisket edema, acute fibrinous pneumonia, proctitis, acute colitis, hemorrhagic typhilitis, chronic bronchopneumonia with abscessation and pleuritis have been found to be common lesions of pneumonic pasteurellosis in pigs. Post-mortem findings and pathological changes suggestive of swine pasteurellosis have also been reported by other workers.

CONCLUSION

The outbreak of pasteurellosis is attributed to impairment of host defences mechanism, strain and virulence of causative organism and various other physiological and environmental stress factors. Incidence of swine pasteurellosis in present case appears to have occurred due to high relative humidity during rainy season which is one of the important environmental stress factors. Thus, due to its highly contagious nature and high mortality rate, the disease has played a major role in huge economic loss in pig farmers of Chhattisgarh.

ACKNOWLEDGEMENTS

Authors are thankful to the Dean, Veterinary College, Anjora, Durg, Chhattisgarh and Director, ICAR National Research Centre on Equines, Hisar, Haryana for providing the necessary facilities to carry out the research. The authors declare that there is no interest of conflict.
